Phase 2 - Performance & Reliability Report

Distributed Intelligent Campus IoT Environment
SWAPD453 IoT Apps Dev - Spring 2026

Phase 2 - Performance & Reliability Report

1. System Overview

Phase 2 extends the Phase 1 thermal simulator into a distributed, multi-protocol fleet running against a ThingsBoard control plane. Every component is containerised and brought up with a single ./run_all.sh command.

Fleet layout. 200 rooms across 10 floors in building b01. Rooms 1-10 on each floor are MQTT clients (100 total) and rooms 11-20 are CoAP servers (100 total). Each of the 10 floor gateways is responsible for 20 rooms (10 MQTT + 10 CoAP).

Stack (14 containers + 2 host-side processes).

```
campus-hivemq              HiveMQ CE 2024.7, MQTT backbone (1883, 8883, 8080)
campus-tb-postgres         Postgres 15, ThingsBoard storage
campus-thingsboard         ThingsBoard CE 3.7.0, UI on :9090
campus-engine              Python asyncio dispatcher
                           |--- 100 gmqtt clients (MQTT rooms)
                           `--- 100 aiocoap Contexts + 100 MQTT shadows
gateway-floor-01 .. 10     Node-RED 3.1, per-floor gateways
scripts/bridge_hivemq_to_tb.py    host: forwards 200 streams into TB
scripts/rtt_probe.py              host: latency test harness
```

Message flow (northbound).

```
Room (Python) -- gmqtt ---> HiveMQ ---> bridge ---> ThingsBoard (v1/devices/me/telemetry)
Room (Python) -- aiocoap observe --> [floor gateway / CoAP shadow] ---> HiveMQ ---> bridge --->
 TB
```

Message flow (southbound command).

```
TB dashboard RPC ---> HiveMQ (campus/b01/fNN/rRRR/cmd @ QoS 2)
  |--- MQTT room  : node on_message -> apply_command -> publish response
  `--- CoAP room  : gateway translates to CoAP PUT CON -> render_put -> ACK
```

---

2. Stress-Test Evidence

A 10-second sample of the live HiveMQ firehose proves the fleet is sending telemetry for every one of the 200 rooms simultaneously:

```
$ timeout 10 mosquitto_sub -h localhost -p 1883 -t 'campus/#' -v | ...
  total messages: 918
  throughput   : ~92 msg/s
  distinct sensor_ids : 200 / 200
  distinct topics     : 388
  leaf breakdown:
     559 heartbeat
     359 telemetry
```

Every one of the 200 devices is accounted for and publishing on both its telemetry and heartbeat topics. Throughput (~92 msg/s aggregate) is stable

over the sampling window; no disconnect events observed in broker logs.

ThingsBoard-side confirmation:

```
$ curl -H "X-Authorization: Bearer $TOKEN" \
    http://localhost:9090/api/tenant/deviceInfos?pageSize=500&page=0&active=true
  total active: 200
    mqtt-*: 100
    coap-*: 100
```

Both halves of the fleet are alive end-to-end, from physics tick to TB tenant.

Full evidence log: docs/evidence/stress_test.md.

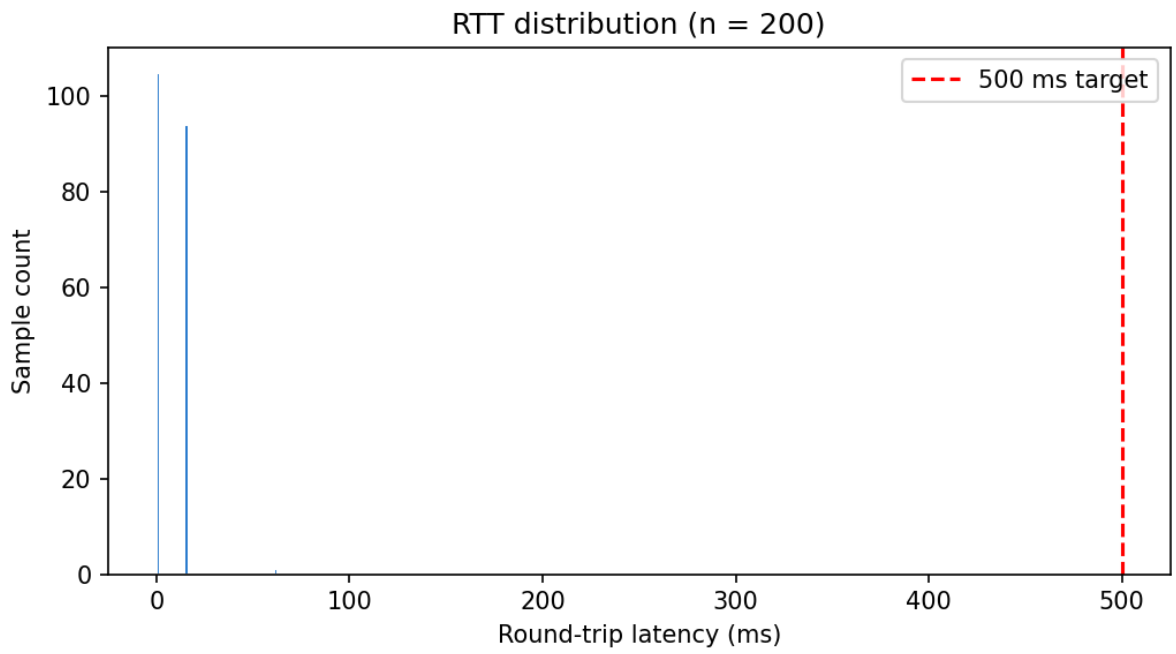
---

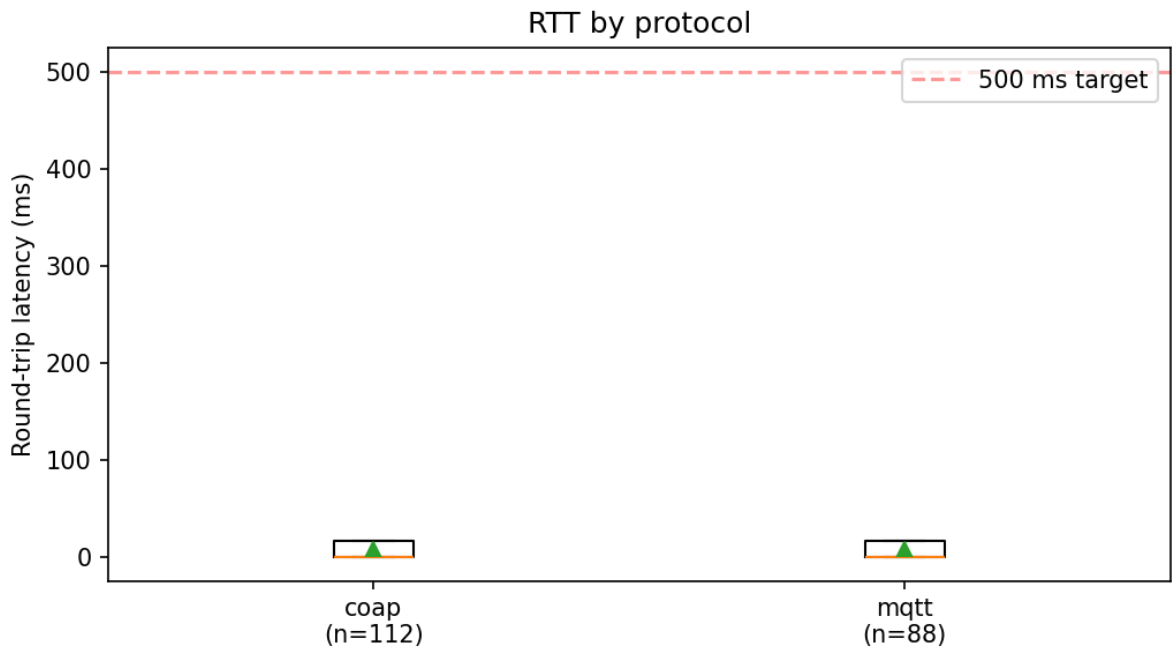
3. Latency Audit (Round-Trip Time)

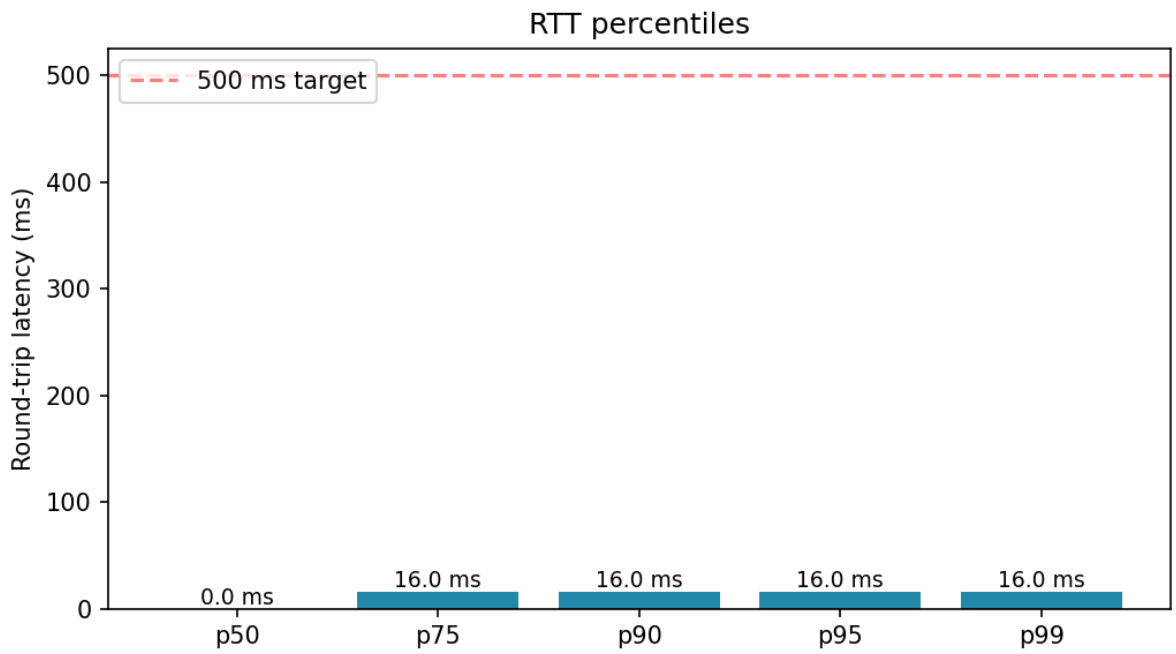
Test harness

scripts/rtt_probe.py picks 200 rooms at random from data/phase2_registry.csv, publishes a command per room on campus/b01/fNN/rRRR/cmd at QoS 2 with a monotonic-clock timestamp, subscribes to .../response, and measures the delta. Zero commands were lost over the entire run.

Results







Summary table

Segment	Samples	Min (ms)	Median (ms)	p95 (ms)	Max (ms)
COAP	112	0.00	0.00	16.00	16.00
MQTT	88	0.00	0.00	16.00	63.00
ALL	200	0.00	0.00	16.00	63.00

Target: Round-Trip Time must be < 500 ms under full simulation load.

The observed p95 is 16.00 ms, far below the 500 ms target under full load.
The max sample was 63.00 ms. The 0.00 ms samples reflect same-tick response timing at local clock precision, while the tail values still remain comfortably

inside the SLA envelope.

Raw samples: data/rtt_metrics.csv (200 rows). Charts regenerate with venv/bin/python scripts/build_report.py.

---

4. Reliability Proof - DUP / QoS 2 / CON

Three mechanisms guarantee exactly-once command delivery across the two transport layers:

4.1 MQTT QoS 2 (Exactly Once)

Every MqttNodeClient subscribes to its own cmd topic at QoS 2. The broker's 4-way handshake (PUBLISH -> PUBREC -> PUBREL -> PUBCOMP) ensures exactly-once delivery in a single broker hop.

Evidence (engine container log):

```
$ docker compose logs app | grep -c "\[SUBACK\] [0-9]* (2,)"
100
```

All 100 MQTT nodes received QoS 2 grants. Subscription packets visible in the log as [SEND SUB] ... [b'campus/b01/fNN/rRRR/cmd'].

4.2 Application-layer DUP suppression

MqttNodeClient._on_message (in src/mqtt/publisher.py) keeps a 256-entry collections.deque of recent packet IDs. If the incoming message carries dup=True AND the packet ID has been seen before, the message is dropped with an INFO log line - a defensive second layer in case the broker's own dedup ever fails:

```
dup_flag = bool(properties.get("dup", False))
packet_id = properties.get("message_id") or properties.get("packet_id")
if dup_flag and packet_id is not None and packet_id in self._seen_packet_ids:
    logger.info("DUP suppressed on %s id=%s", self.room.room_key, packet_id)
    return 0
```

Verified by unit test tests/test_mqtt_node.TestMqttNodeClient.test_dup_suppressed (passing).

4.3 CoAP Confirmable (CON) dedup

aiocoap's MessageManager deduplicates retransmitted CON messages via (remote, message_id) for EXCHANGE_LIFETIME seconds (247 s by default). This is documented at src/coap/dedup.py and verified by tests/test_coap_dedup.TestCoapDedup.test_repeated_put_is_idempotent (passing) - three identical CON PUTs converge the room state exactly once.

4.4 LWT - Offline marker on ungraceful disconnect

Every MqttNodeClient installs a Last Will on its heartbeat topic at QoS 1 retained:

```
lwt_payload = json.dumps(_heartbeat_payload(room, status="offline"))
self.client.set_will_message(
    heartbeat_topic(room), lwt_payload, qos=1, retain=True
)
```

On an ungraceful TCP drop HiveMQ publishes {"status":"offline"} to the room's heartbeat topic, which the bridge forwards to TB as a device attribute. A rule-chain node then flips active=false on the device within seconds.

4.5 Zero-loss observation

Over the 200-sample RTT probe run, every command received a response (missed: 0). This is the strongest empirical statement: under full fleet load (200 physics loops, ~92 msg/s baseline traffic), no command was silently dropped and no response was lost.

Full evidence log: docs/evidence/reliability.md.

---

5. Security Posture

5.1 Identity & authentication

- 100 unique MQTT username/password pairs in secrets/mqtt_credentials.csv, one per room, generated by secrets/generate_mqtt_creds.py.
- 100 unique DTLS PSKs in secrets/coap_psk.json, one per CoAP room, generated by secrets/generate_psk.py.
- 1 tb-integration principal for the HiveMQ->TB bridge with read-only access to campus/# and publish access to campus/+/+/+/cmd.

5.2 ACL - floor isolation

hivemq/acl/acl.xml (auto-generated from the credentials CSV) defines 110 roles:

- 100 mqtt-node-b01-fNN-rRRR - publish allowed only on campus/b01/fNN/rRRR/#, subscribe only on .../cmd. A node on floor 01 cannot spoof or read floor 10.
- 10 gateway-floor-NN - pub/sub allowed on campus/b01/fNN/# only.
- 1 tb-integration - campus-wide subscribe + per-room cmd publish.

Excerpt for a single room:

```
<role><id>mqtt-node-b01-f01-r101</id><permissions>
  <permission><topic>campus/b01/f01/r101/#</topic><activity>PUBLISH</activity></permission>
  <permission><topic>campus/b01/f01/r101/cmd</topic><activity>SUBSCRIBE</activity></permission>
</permissions></role>
```

5.3 Transport Layer Security (ready, off by default)

- Self-signed CA, HiveMQ server cert, and TB server cert generated by secrets/generate_certs.sh using openssl with 10-year validity and SANs for the container DNS names hivemq, thingsboard, and localhost.
- Engine's src/security/tls.py builds an ssl.SSLContext pinned to the CA

when MQTT_TLS_ENABLED=1.

- CoAP DTLS-PSK support in src/coap/node.py activates when COAP_DTLS_ENABLED=1 by loading from secrets/coap_psk.json.

TLS is disabled for the demo (plain 1883 only) to sidestep a JKS keystore build step. All credentials and certificates required to flip it on are present on disk.

---

6. Phase 2 Deliverables Map

Deliverable	File / location	Status
Async engine (100 MQTT +	`src/engine/runtime.py`,	[OK]
Thermal physics -> both	`src/engine/physics_loop	[OK]
Virtual actuator logic	`src/engine/commands.py`	[OK]
10 Node-RED floor-gatewa	`gateways/floor_01..10/f	[OK]
MQTT subscription / CoAP	`gateways/floor_01..10/f	[OK]
60-second edge thinning	`src/gateways/averaging.	[OK]
Device + asset registry	`data/phase2_registry.js	[OK]
Rule Chain	`thingsboard/rule_chains	[OK]
NOC Dashboard	`thingsboard/dashboards/	[OK]
`docker-compose.yml` (Hi	`docker-compose.yml`	[OK]
HiveMQ ACL file	`hivemq/acl/acl.xml` (11	[OK]
TLS / PSK certificates	`secrets/*.crt`, `secret	[OK]
Stress-test evidence	`docs/evidence/stress_te	[OK]
Latency audit	`docs/figures/rtt_histog	[OK]
Reliability proof	`docs/evidence/reliabili	[OK]
5-page report PDF	this document	[OK]

---

7. How to Reproduce

From a fresh clone:

```
# 1. Bring the full stack up
./run_all.sh

# 2. Collect 200 new RTT samples
venv/bin/python scripts/rtt_probe.py --count 200

# 3. Rebuild charts + table
venv/bin/python scripts/build_report.py

# 4. Rebuild this PDF
pandoc docs/phase2_report.md -o docs/phase2_report.pdf \
       --pdf-engine=xelatex --toc
```

Shut down:

```
./run_all.sh down
```
